

Views / Templates

Each template language is exposed via its own rendering method. These methods simply return a string:

```
get '/' do
  erb :index
end
```

This renders `views/index.erb`.

Instead of a template name, you can also just pass in the template content directly:

```
get '/' do
  code = "<%= Time.now %>"
  erb code
end
```

Templates take a second argument, the options hash:

```
get '/' do
  erb :index, :layout => :post
end
```

This will render `views/index.erb` embedded in the `views/post.erb` (default is `views/layout.erb`, if it exists).

Any options not understood by Sinatra will be passed on to the template engine:

```
get '/' do
  haml :index, :format => :html5
end
```

You can also set options per template language in general:

```
set :haml, :format => :html5

get '/' do
  haml :index
end
```

Options passed to the render method override options set via `set`.

Available Options:

locals

List of locals passed to the document. Handy with partials. Example: `erb "<%= foo="" %="">", :locals => { :foo => "bar" }`

default_encoding

String encoding to use if uncertain. Defaults to `settings.default_encoding`.

views

Views folder to load templates from. Defaults to `settings.views`.

layout

Whether to use a layout (`true` or `false`). If it's a Symbol, specifies what template to use. Example: `erb :index, :layout => !request.xhr?`

content_type

Content-Type the template produces. Default depends on template language.

scope

Scope to render template under. Defaults to the application instance. If you change this, instance variables and helper methods will not be available.

layout_engine

Template engine to use for rendering the layout. Useful for languages that do not support layouts otherwise. Defaults to the engine used for the template. Example: `set :rdoc, :layout_engine => :erb`

layout_options

Special options only used for rendering the layout. Example: `set :rdoc, :layout_options => { :views => 'views/layouts' }`

Templates are assumed to be located directly under the `./views` directory. To use a different views directory:

```
set :views, settings.root + '/templates'
```

One important thing to remember is that you always have to reference templates with symbols, even if they're in a subdirectory (in this case, use: `:subdir/template` or `'subdir/template'.to_sym`). You must use a symbol because otherwise rendering methods will render any strings passed to them directly.

Literal Templates

```
get '/' do
  haml '%div.title Hello World'
end
```

Renders the template string.

Available Template Languages

Some languages have multiple implementations. To specify what implementation to use (and to be thread-safe), you should simply require it first:

```
require 'rdiscount' # or require 'bluecloth'
get('/') { markdown :index }
```

HamI Templates

Dependency	haml
File Extension	<code>.haml</code>
Example	<code>haml :index, :format => :html5</code>

Erb Templates

Dependency	erubis or <code>erb</code> (included in Ruby)
File Extensions	<code>.erb</code> , <code>.rhtml</code> or <code>.erubis</code> (Erubis only)
Example	<code>erb :index</code>

Builder Templates

Dependency	builder
File Extension	<code>.builder</code>
Example	<code>builder { xml xml.em "hi" }</code>

It also takes a block for inline templates (see example).

Nokogiri Templates

Dependency	nokogiri
File Extension	<code>.nokogiri</code>
Example	<code>nokogiri { xml xml.em "hi" }</code>

It also takes a block for inline templates (see example).

Sass Templates

Dependency	sass
File Extension	<code>.sass</code>
Example	<code>sass :stylesheet, :style => :expanded</code>

SCSS Templates

Dependency	sass
File Extension	<code>.scss</code>
Example	<code>scss :stylesheet, :style => :expanded</code>

Less Templates

Dependency	less
File Extension	<code>.less</code>
Example	<code>less :stylesheet</code>

Liquid Templates

Dependency	liquid
File Extension	<code>.liquid</code>
Example	<code>liquid :index, :locals => { :key => 'value' }</code>

Since you cannot call Ruby methods (except for `yield`) from a Liquid template, you almost always want to pass locals to it.

Markdown Templates

Dependency	Anyone of: RDiscount , RedCarpet , BlueCloth , kramdown , maruku
File Extensions	<code>.markdown</code> , <code>.mkd</code> and <code>.md</code>
Example	<code>markdown :index, :layout_engine => :erb</code>

It is not possible to call methods from markdown, nor to pass locals to it. You therefore will usually use it in combination with another rendering engine:

```
erb :overview, :locals => { :text => markdown(:introduction) }
```

Note that you may also call the `markdown` method from within other templates:

```
%h1 Hello From Haml!  
%p= markdown(:greetings)
```

Since you cannot call Ruby from Markdown, you cannot use layouts written in Markdown. However, it is possible to use another rendering engine for the template than for the layout by passing the `:layout_engine` option.

Textile Templates

Dependency	RedCloth
File Extension	<code>.textile</code>
Example	<code>textile :index, :layout_engine => :erb</code>

It is not possible to call methods from textile, nor to pass locals to it. You therefore will usually use it in

combination with another rendering engine:

```
erb :overview, :locals => { :text => textile(:introduction) }
```

Note that you may also call the `textile` method from within other templates:

```
%h1 Hello From Haml!  
%p= textile(:greetings)
```

Since you cannot call Ruby from Textile, you cannot use layouts written in Textile. However, it is possible to use another rendering engine for the template than for the layout by passing the `:layout_engine` option.

RDoc Templates

Dependency	RDoc
File Extension	<code>.rdoc</code>
Example	<code>rdoc :README, :layout_engine => :erb</code>

It is not possible to call methods from `rdoc`, nor to pass locals to it. You therefore will usually use it in combination with another rendering engine:

```
erb :overview, :locals => { :text => rdoc(:introduction) }
```

Note that you may also call the `rdoc` method from within other templates:

```
%h1 Hello From Haml!  
%p= rdoc(:greetings)
```

Since you cannot call Ruby from RDoc, you cannot use layouts written in RDoc. However, it is possible to use another rendering engine for the template than for the layout by passing the `:layout_engine` option.

AsciiDoc Templates

Dependency	Asciidoctor
File Extension	<code>.asciidoc</code> , <code>.adoc</code> and <code>.ad</code>
Example	<code>asciidoc :README, :layout_engine => :erb</code>

Since you cannot call Ruby methods directly from an AsciiDoc template, you almost always want to pass locals to it.

Radius Templates

Dependency	Radius
------------	------------------------

File Extension	<code>.radius</code>
Example	<code>radius :index, :locals => { :key => 'value' }</code>

Since you cannot call Ruby methods directly from a Radius template, you almost always want to pass locals to it.

Markaby Templates

Dependency	Markaby
File Extension	<code>.mab</code>
Example	<code>markaby { h1 "Welcome!" }</code>

It also takes a block for inline templates (see example).

RABL Templates

Dependency	Rabl
File Extension	<code>.rabl</code>
Example	<code>rabl :index</code>

Slim Templates

Dependency	Slim Lang
File Extension	<code>.slim</code>
Example	<code>slim :index</code>

Creole Templates

Dependency	Creole
File Extension	<code>.creole</code>
Example	<code>creole :wiki, :layout_engine => :erb</code>

It is not possible to call methods from creole, nor to pass locals to it. You therefore will usually use it in combination with another rendering engine:

```
erb :overview, :locals => { :text => creole(:introduction) }
```

Note that you may also call the `creole` method from within other templates:

```
%h1 Hello From Haml!
%p= creole(:greetings)
```

Since you cannot call Ruby from Creole, you cannot use layouts written in Creole. However, it is possible to use another rendering engine for the template than for the layout by passing the `:layout_engine` option.

MediaWiki Templates

Dependency	WikiCloth
File Extension	<code>.mediawiki</code> and <code>.mw</code>
Example	<code>mediawiki :wiki, :layout_engine => :erb</code>

It is not possible to call methods from MediaWiki markup, nor to pass locals to it. You therefore will usually use it in combination with another rendering engine:

```
erb :overview, :locals => { :text => mediawiki(:introduction) }
```

Note that you may also call the `mediawiki` method from within other templates:

```
%h1 Hello From Haml!  
%p= mediawiki(:greetings)
```

Since you cannot call Ruby from MediaWiki, you cannot use layouts written in MediaWiki. However, it is possible to use another rendering engine for the template than for the layout by passing the `:layout_engine` option.

CoffeeScript Templates

Dependency	CoffeeScript and a way to execute javascript
File Extension	<code>.coffee</code>
Example	<code>coffee :index</code>

Stylus Templates

Dependency	Stylus and a way to execute javascript
File Extension	<code>.styl</code>
Example	<code>stylus :index</code>

Before being able to use Stylus templates, you need to load `stylus` and `stylus/tilt` first:

```
require 'sinatra'  
require 'stylus'  
require 'stylus/tilt'  
  
get '/' do  
  stylus :example  
end
```

```
end
```

Yajl Templates

Dependency [yajl-ruby](#)

File
Extension `.yajl`

Example `yajl :index, :locals => { :key => 'qux' }, :callback => 'present',
:variable => 'resource'`

The template source is evaluated as a Ruby string, and the resulting json variable is converted using `#to_json`:

```
json = { :foo => 'bar' }  
json[:baz] = key
```

The `:callback` and `:variable` options can be used to decorate the rendered object:

```
var resource = {"foo":"bar","baz":"qux"};  
present(resource);
```

WLang Templates

Dependency [WLang](#)

File Extension `.wlang`

Example `wlang :index, :locals => { :key => 'value' }`

Since calling ruby methods is not idiomatic in WLang, you almost always want to pass locals to it. Layouts written in WLang and `yield` are supported, though.

Accessing Variables in Templates

Templates are evaluated within the same context as route handlers. Instance variables set in route handlers are directly accessible by templates:

```
get('/:id' do  
  @foo = Foo.find(params['id'])  
  haml '%h1= @foo.name'  
end
```

Or, specify an explicit Hash of local variables:

```
get('/:id' do  
  foo = Foo.find(params['id'])
```

```
haml '%h1= bar.name', :locals => { :bar => foo }  
end
```

This is typically used when rendering templates as partials from within other templates.

Templates with `yield` and nested layouts

A layout is usually just a template that calls `yield`. Such a template can be used either through the `:template` option as described above, or it can be rendered with a block as follows:

```
erb :post, :layout => false do  
  erb :index  
end
```

This code is mostly equivalent to `erb :index, :layout => :post`.

Passing blocks to rendering methods is most useful for creating nested layouts:

```
erb :main_layout, :layout => false do  
  erb :admin_layout do  
    erb :user  
  end  
end
```

This can also be done in fewer lines of code with:

```
erb :admin_layout, :layout => :main_layout do  
  erb :user  
end
```

Currently, the following rendering methods accept a block: `erb`, `haml`, `liquid`, `slim`, `wlang`. Also the general `render` method accepts a block.

Named Templates

Templates may also be defined using the top-level `template` method:

```
template :layout do  
  "%html\n  =yield\n"  
end  
  
template :index do  
  '%div.title Hello World!'  
end  
  
get '/' do
```

```
haml :index
end
```

If a template named "layout" exists, it will be used each time a template is rendered. You can individually disable layouts by passing `:layout => false` or disable them by default via `set :haml, :layout => false`:

```
get '/' do
  haml :index, :layout => !request.xhr?
end
```

Associating File Extensions

To associate a file extension with a template engine, use `Tilt.register`. For instance, if you like to use the file extension `tt` for Textile templates, you can do the following:

```
Tilt.register :tt, Tilt[:textile]
```

Adding Your Own Template Engine

First, register your engine with Tilt, then create a rendering method:

```
Tilt.register :myat, MyAwesomeTemplateEngine

helpers do
  def myat(*args) render(:myat, *args) end
end

get '/' do
  myat :index
end
```

Renders `./views/index.myat`. See <https://github.com/rtomayko/tilt> to learn more about Tilt.

Using Custom Logic for Template Lookup

To implement your own template lookup mechanism you can write your own `#find_template` method:

```
configure do
  set :views [ './views/a', './views/b' ]
end

def find_template(views, name, engine, &block)
  Array(views).each do |v|
    super(v, name, engine, &block)
  end
end
```

Inline Templates

Templates may be defined at the end of the source file:

```
require 'sinatra'

get '/' do
  haml :index
end

__END__

@@ layout
%html
  = yield

@@ index
%div.title Hello world.
```

NOTE: Inline templates defined in the source file that requires sinatra are automatically loaded. Call `enable :inline_templates` explicitly if you have inline templates in other source files.
